## DIAZABICYCLONONENE DERIVATIVES AND THEIR USE AS RENIN INHIBITORS

The invention relates to novel five-membered heteroaryl derivatives of the general formula

5 (I). The invention also concerns related aspects including processes for the preparation of the compounds, pharmaceutical compositions containing one or more compounds of formula (I) and especially their use as renin inhibitors in cardiovascular events and renal insufficiency.

In the renin-angiotensin system (RAS) the biologically active angiotensin II  
10 (Ang II) is generated by a two-step mechanism. The highly specific enzyme renin cleaves angiotensinogen to angiotensin I (Ang I), which is then further processed to Ang II by the less specific angiotensin-converting enzyme (ACE). Ang II is known to work on at least two receptor subtypes called AT<sub>1</sub> and AT<sub>2</sub>. Whereas AT<sub>1</sub> seems to transmit most of the known functions of Ang II, the role of AT<sub>2</sub> is still unknown.

15 Modulation of the RAS represents a major advance in the treatment of cardiovascular diseases. ACE inhibitors and AT<sub>1</sub> blockers have been accepted to treat hypertension (Waeber B. *et al.*, "The renin-angiotensin system: role in experimental and human hypertension", in Berkenhager W. H., Reid J. L. (eds): *Hypertension*, Amsterdam, Elsevier Science Publishing Co, 1996, 489-519; Weber M. A., *Am. J. Hypertens.*, 1992, 5, 247S). In  
20 addition, ACE inhibitors are used for renal protection (Rosenberg M. E. *et al.*, *Kidney International*, 1994, 45, 403; Breyer J. A. *et al.*, *Kidney International*, 1994, 45, S156), in the prevention of congestive heart failure (Vaughan D. E. *et al.*, *Cardiovasc. Res.*, 1994, 28, 159; Fouad-Tarazi F. *et al.*, *Am. J. Med.*, 1988, 84 (Suppl. 3A), 83) and myocardial infarction (Pfeffer M. A. *et al.*, *N. Engl. J. Med.*, 1992, 327, 669).

25 The rationale to develop renin inhibitors is the specificity of renin (Kleinert H. D., *Cardiovasc. Drugs*, 1995, 9, 645). The only substrate known for renin is angiotensinogen, which can only be processed (under physiological conditions) by renin. In contrast, ACE can also cleave bradykinin besides Ang I and can be by-passed by chymase, a serine protease (Husain A., *J. Hypertens.*, 1993, 11, 1155). In patients inhibition of ACE thus  
30 leads to bradykinin accumulation causing cough (5-20%) and potentially life-threatening angioneurotic edema (0.1-0.2%) (Israili Z. H. *et al.*, *Annals of Internal Medicine*, 1992, 117, 234). Chymase is not inhibited by ACE inhibitors. Therefore, the formation of Ang II is still possible in patients treated with ACE inhibitors. Blockade of the AT<sub>1</sub> receptor (e.g.

by losartan) on the other hand overexposes other AT-receptor subtypes (e.g. AT<sub>2</sub>) to Ang II, whose concentration is significantly increased by the blockade of AT<sub>1</sub> receptors. In summary, renin inhibitors are expected to demonstrate a different pharmaceutical profile than ACE inhibitors and AT<sub>1</sub> blockers with regard to efficacy in blocking the RAS and in safety aspects.

Only limited clinical experience (Azizi M. *et al.*, *J. Hypertens.*, 1994, 12, 419; Neutel J. M. *et al.*, *Am. Heart*, 1991, 122, 1094) has been created with renin inhibitors because of their insufficient oral activity due to their peptidomimetic character (Kleinert H. D., *Cardiovasc. Drugs*, 1995, 9, 645). The clinical development of several compounds has been stopped because of this problem together with the high cost of goods. Only one compound containing four chiral centers has entered clinical trials (Rahuel J. *et al.*, *Chem. Biol.*, 2000, 7, 493; Mealy N. E., *Drugs of the Future*, 2001, 26, 1139). Thus, renin inhibitors with good oral bioavailability and long duration of action are required. Recently, the first non-peptide renin inhibitors were described which show high *in vitro* activity (Oefner C. *et al.*, *Chem. Biol.*, 1999, 6, 127; Patent Application WO97/09311; Märki H. P. *et al.*, *Il Farmaco*, 2001, 56, 21). However, the development status of these compounds is not known.

The present invention relates to the identification of renin inhibitors of a non-peptidic nature and of low molecular weight. Described are orally active renin inhibitors of long duration of action which are active in indications beyond blood pressure regulation where the tissular renin-chymase system may be activated leading to pathophysiologically altered local functions such as renal, cardiac and vascular remodeling, atherosclerosis, and possibly restenosis. So, the present invention describes these non-peptidic renin inhibitors. The present invention describes non-peptidic renin inhibitors.

15 topical administration. They can be administered, for example, perorally, e. g. in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions, rectally, e. g. in the form of suppositories, parenterally, e. g. in the form of injection solutions or infusion solutions, or topically, e. g. in the form of ointments, creams or oils.

- 20 The production of pharmaceutical preparations can be effected in a manner which will be familiar to any person skilled in the art by bringing the described compounds of formula (I) and their pharmaceutically acceptable acid addition salts, optionally in combination with other therapeutically valuable substances, into a galenical administration form together with suitable, non-toxic, inert, therapeutically compatible solid or liquid carrier materials  
25 and, if desired, usual pharmaceutical adjuvants.

- Suitable carrier materials are not only inorganic carrier materials, but also organic carrier materials. Thus, for example, lactose, corn starch or derivatives thereof, talc, stearic acid or its salts can be used as carrier materials for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carrier materials for soft gelatine capsules are, for example,  
30 vegetable oils, waxes, fats and semi-solid and liquid polyols (depending on the nature of the active ingredient no carriers are, however, required in the case of soft gelatine capsules). Suitable carrier materials for the production of solutions and syrups are, for example, water, polyols, sucrose, invert sugar and the like. Suitable carrier materials for injections are, for example, water, alcohols, polyols, glycerols and vegetable oils. Suitable

carrier materials for suppositories are, for example, natural or hardened oils, waxes, fats and semi-liquid or liquid polyols. Suitable carrier materials for topical preparations are glycerides, semi-synthetic and synthetic glycerides, hydrogenated oils, liquid waxes, liquid paraffins, liquid fatty alcohols, sterols, polyethylene glycols and cellulose derivatives.

- 5 Usual stabilizers, preservatives, wetting and emulsifying agents, consistency-improving agents, flavour-improving agents, salts for varying the osmotic pressure, buffer substances, solubilizers, colorants and masking agents and antioxidants come into consideration as pharmaceutical adjuvants.

The dosage of compounds of formula (I) can vary within wide limits depending on the disease to be controlled, the age and the individual condition of the patient and the mode of administration, and will, of course, be fitted to the individual requirements in each particular case.

Another aspect of the invention is related to a process for the preparation of a pharmaceutical composition comprising a derivative of the general formula (I). According to said process, one or more active ingredients of the general formula (I) are mixing with inert excipients in a manner known *per se*.

The compounds of general formula I can be manufactured by the methods outlined below, by the methods described in the examples or by analogous methods.

20 Preparation of the precursors:

Precursors are compounds which were prepared as key intermediates and/or building blocks and which were suitable for further transformations in parallel chemistry. Most of the chemistry applicable here has already been described in the patent applications WO03/093267 and WO04/002957.

- 25 As illustrated in Scheme 1 the known compound A can be derivatised into the corresponding triflate B. A *Negishi*-type coupling (or any other coupling catalysed by a transition metal) leads to a compound of type C whereby R<sup>a</sup> represents a precursor for the fragment U-V, as defined in general formula (I). R<sup>a</sup> can be easily transformed into the fragment U-V using elemental chemical operations. After protecting group manipulation  
30 (→ compound of type D), ajustement of the W-V-U linker is possible for instance by deprotection and a *Mitsunobu*-type reaction, leading to a compound of type E. Hydrolysis of the ester leads to a carboxylic acid of type F, then an amide coupling for instance to a compound of type G. Removal of the Boc-protecting group and alkylation, or acylation, leads to a precursor of type H.

13  
Scheme 1

- 5 The bromoaryl components can be prepared as described in Scheme 2. A *Mitsunobu* coupling (→ compounds of type J) or the alkylation of an alcohol with a benzylic chloride (or bromide, → compounds of type K) are often the most convenient methods. Derivatives L and M were prepared in one step from 1-(3-chloropropoxymethyl)-2-methoxybenzene (Vieira E. *et al.*, *Bioorg. Med. Chem. Letters*, 1999, 9, 1397) or 3-(5-bromopyridin-2-yloxy)propan-1-ol (Patent Application WO 98/39328) according to these methods. Other methods for the preparation of ethers or thioethers, like a *Williamson* synthesis, can be used as well (see e.g. March, J, "Advanced Organic Chemistry," 3<sup>rd</sup> ed., John Wiley and sons, 1985).

#### 5 Preparation of the secondary amines

The secondary amines can be prepared for instance as described in Scheme 3. The pyridine derivative N can be prepared from commercially available 2-chloro-isonicotinoyl chloride. Deprotonation at the 3-position of this derivative, for instance with BuLi, and subsequent alkylation with a suitable electrophile leads to a derivative of type O, whereby

10  $R^d$  represents a suitable substituent that can be introduced by this chemistry, and can be transformed later into a desired substituent as described in general formula I. Reduction of the amide into an aldehyde with DIBAL leads to a compound of type P, then a reductive amination leads to an amine of type Q, whereas  $R^1$  stand for a substituent as defined above.

Finally substitution of the chlorine atom with an alcohol of type  $HO(CH_2)_vR^5$ , whereby

15  $R^5$  may still be protected, leads to an amine of type R. An alcohol of type  $HO(CH_2)_2O(CH_2)_wR^5$  can be introduced in the same way.

15  
Scheme 3

In the case of phenyl derivatives it is better to start from a compound of type S, wherein  
 5 PG' represents a suitable protecting group. Amide coupling with *N*-methylaniline leads to  
 a derivative of type T, then deprotection to a derivative of type U. Ether bond formation,  
 via a *Mitsunobu*-type reaction or from a corresponding alkyl halide, leads to a compound of  
 type V. Reduction leads to an aldehyde of type W, then reductive amination to an amine  
 of type X. An alcohol of type  $\text{HO}(\text{CH}_2)_2\text{O}(\text{CH}_2)_w\text{R}^5$  can be introduced in the same way.

Scheme 45 Preparation of final compounds

From precursors prepared as described above, the final compounds may be prepared using parallel chemistry techniques. For the specific examples, see the experimental part.

Diazabicyclononenes of type of H can be deprotected using standard procedures (Scheme 5). Purification by preparative HPLC might give the corresponding TFA salts or formate

10 salts.

20 The following assay was carried out in order to determine the activity of the compounds of general formula I and their salts.

#### Inhibition of human recombinant renin by the compounds of the invention

The enzymatic in vitro assay was performed in 384-well polypropylene plates (Nunc). The assay buffer consisted of 10 mM PBS (Gibco BRL) including 1 mM EDTA and 0.1% BSA. The incubates were composed of 50 µL per well of an enzyme mix and 2.5 µL of renin inhibitors in DMSO. The enzyme mix was premixed at 4°C and consists of the following components:

- human recombinant renin (0.16 ng/mL) • synthetic human angiotensin(1-14) (0.5 µM)
- 30 • hydroxyquinoline sulfate (1 mM)

The mixtures were then incubated at 37°C for 3 h.

To determine the enzymatic activity and its inhibition, the accumulated Ang I was detected by an enzyme immunoassay (EIA) in 384-well plates (Nunc). 5 µL of the incubates or standards were transferred to immuno plates which were previously coated with a covalent

complex of Ang I and bovine serum albumin (Ang I – BSA). 75  $\mu$ L of Ang I-antibodies in  
essaybuffer above including 0.01% Tween 20 were added and a primary incubation made  
at 4 °C overnight. The plates were washed 3 times with PBS including 0.01% Tween 20,  
and then incubated for 2 h at rt with an antirabbit-peroxidase coupled antibody (WA 934,  
5 Amersham). After washing the plates 3 times, the *peroxidase substrate* ABTS (2,2'-azino-  
di-(3-ethyl-benzthiazolinsulfonate), was added and the plates incubated for 60 min at room  
temperature. After stopping the reaction with 0.1 M citric acid pH 4.3 the plate was  
evaluated in a microplate reader at 405 nm. The percentage of inhibition was calculated of  
each concentration point and the concentration of renin inhibition was determined that  
10 inhibited the enzyme activity by 50% (IC<sub>50</sub>). The IC<sub>50</sub>-values of all compounds tested are  
below 100 nM. However selected compounds exhibit a very good bioavailability and are  
metabolically more stable than prior art compounds.
